ACKNOWLEDGEMENT

I would like to express my sincere gratitude and appreciation to all those who have contributed to the completion of this master's thesis. First and foremost, I am deeply indebted to my supervisor, Associate Professor Dr. Chung Hung Hui, for his invaluable guidance, support, and expertise throughout the entire research process. His insightful feedback, constructive criticism, and continuous encouragement were instrumental in shaping this thesis and enhancing its quality. I am truly fortunate to have had his guidance throughout this journey. I would also like to acknowledge the financial support of Malaysian Ministry of Higher Education under Fundamental Research Grant Scheme (F07/FRGS/85428/2022).

I would also like to extend my heartfelt thanks to my Animal Biotechnology Lab mates: Melinda and Ivy. Their collaborative spirit, intellectual discussions, and constructive feedback have greatly enriched my research experience. I am grateful for the camaraderie, friendship, and shared knowledge we have fostered, which have undoubtedly contributed to the success of this thesis.

My gratitude extends to my family members: my father Kho Boo Teng, my mother Fam Say Tho, and my sister Wendy Kho Jia Min for their unwavering support and encouragement throughout this academic journey. Their understanding, patience, and belief in my abilities have been a constant source of motivation. Furthermore, I would like to extend my sincere appreciation to my close friends Eirene and Min Kim for their company.

ABSTRACT

The unregulated and/or incorrect use of antimicrobial agents against diseases of farmed aquatic species poses a considerable threat to the development and growth of a sustainable aquaculture industry. Hence, vaccination has emerged as a pivotal strategy to mitigate this threat. This study marks the first utilization of reverse vaccinology to develop subunit vaccines against *Pseudomonas koreensis* infection in Empurau (*Tor tambroides*). WGS analysis revealed that the genomic size of *P. koreensis* CM-01 is 6,171,880 bp and has a G+C content of 60.5%. The proteome (5,538 proteins) was screened against various filters to prioritize proteins based on features that are associated with virulence, subcellular localization, transmembrane helical structure, antigenicity, essentiality, non-homology with the host proteome, molecular weight, and stability, which led to the identification of eight potential vaccine candidates. These potential vaccine candidates were cloned and expressed, with six achieving successful expression and purification. The antigens were formulated into two distinct vaccine mixtures, Vac A and Vac B, and their protective efficacy was assessed through *in vivo* challenge experiments. Vac A and Vac B demonstrated high protective efficacies of 100% and 81.2%, respectively. Histological analyses revealed reduced tissue damage in vaccinated fish after experimental infection, with Vac A showing no adverse effects, whereas Vac B exhibited mild degenerative changes. Quantitative real-time PCR results showed a significant upregulation of *TNF- α* and downregulation of *IL-1 β* in the kidneys, spleen, gills, and intestine in both Vac A- and Vac B immunized fish after challenged with *P. koreensis*. Additionally, *IL-8* exhibits tissue-specific differential expression, with significant upregulation in the kidney, gills, and intestine, and downregulation in the spleen, particularly notable in Vac A immunized fish. The research

underscores the effectiveness of the reverse vaccinology approach in fish and demonstrates the promising potential of Vac A and Vac B as recombinant subunit vaccines.

Keywords: *Pseudomonas. koreensis*; *Tor tambroides*; Reverse vaccinology; Subunit vaccines; Protective efficacy

Pemilihan Kandidat Vaksin untuk Pseudomonas koreensis Melalui Vaksinologi Terbalik dan Percobaan Keberkesanan Awal dalam Tor tambroides (Empurau)

ABSTRAK

*Penggunaan agen antimikrobial yang tidak terkawal dan/atau tidak betul terhadap penyakit-penyakit spesies akuatik yang diternak membawa ancaman yang signifikan terhadap perkembangan dan pertumbuhan industri akuakultur yang mampan. Oleh itu, vaksinasi telah muncul sebagai strategi penting untuk mengurangkan ancaman ini. Kajian ini menandakan penggunaan pertama vaksinologi terbalik untuk membangunkan vaksin subunit terhadap jangkitan Pseudomonas koreensis dalam empurau (Tor tambroides). Analisis penjujukan genom keseluruhan (WGS) mendedahkan bahawa saiz genom P. koreensis CM-01 adalah 6,171,880 bp dan mempunyai kandungan G+C sebanyak 60.5%. Proteom (5,538 protein) telah disaring terhadap pelbagai penapis untuk mengutamakan protein berdasarkan ciri-ciri yang dikaitkan dengan virulensi, lokalisasi subselular, struktur heliks transmembran, antigenisiti, keesensialan, ketiadaan homologi dengan proteom hos, berat molekul, dan kestabilan, yang membawa kepada pengenalpastian lapan kandidat vaksin berpotensi. Kandidat vaksin berpotensi ini diklon dan diekspresikan, dengan enam mencapai kejayaan ekspresi dan penulenan. Antigen tersebut dirumuskan kepada dua campuran vaksin yang berbeza, Vac A dan Vac B, dan keberkesanan perlingkungannya dinilai melalui eksperimen cabaran *in vivo*. Vac A dan Vac B menunjukkan keberkesanan perlindungan yang tinggi masing-masing sebanyak 100% dan 81.2%. Analisis histologi mendedahkan pengurangan kerosakan tisu pada ikan yang divaksin selepas jangkitan percubaan, dengan Vac A tidak menunjukkan kesan buruk, manakala Vac B menunjukkan perubahan degeneratif yang ringan. Keputusan PCR real-time kuantitatif menunjukkan peningkatan yang signifikan dalam ekspresi TNF- α dan penurunan ekspresi IL-1 β dalam*

buah pinggang, limpa, insang dan usus dalam kedua-dua ikan yang diimmunisasi Vac A- dan Vac B selepas dicabar dengan P. koreensis. Selain itu, IL-8 menunjukkan ekspresi pembezaan khusus tisu, dengan peningkatan yang signifikan di buah pinggang, insang, dan usus dan penurunan di limpa, terutamanya ketara dalam ikan yang diimmunisasi dengan Vac A. Kajian ini menekankan keberkesanan pendekatan vaccinology terbalik dalam ikan dan menunjukkan potensi menjanjikan Vac A dan Vac B sebagai vaksin subunit rekombinan.

CHAPTER 1

INTRODUCTION

Aquaculture involves the cultivation of aquatic organisms such as fish, crustaceans, mollusks, and even aquatic plants in a regulated fashion to allow the independence of wild catches. It is emerging as an important economic agribusiness, worldwide. According to Food and Agriculture Organization (FAO), global aquaculture production hit a record-breaking 122.6 million metric tons (MT) in 2020, with China alone contributing 57% of the global aquaculture volume (FAO, 2022). The increasing demand for aquaculture production stems from the fact that the wild harvesting of numerous seafood species has already reached or surpassed the maximum sustainable yield (Dulvy et al., 2021). As a result, aquaculture offers a viable alternative, enabling farmers to cultivate these species in controlled environments and thus easing the burden on wild stocks. Consequently, this approach holds the potential to restore depleted wild stocks and aid in the recovery of endangered and threatened species in the future (Osathanunkul & Suwannapoom, 2023). However, the fish that are kept in captivity are more prone to infection as the fish are reared at higher densities than wild individuals, which enables pathogens to spread quickly (Bouwmeester et al., 2021). Consequently, disease outbreaks pose a significant challenge to productivity and lead to substantial economic losses in the aquaculture industry.

Tor tambroides, locally known as “kelah merah” in Peninsular Malaysia or empurau in Sarawak, is a promising freshwater fish species from the Cyprinidae family. The cultivation interest in this species arises from its significant cultural and socioeconomic importance, encompassing its roles as food, ornamental, and sporting fish (Lau et al., 2021). Due to the decline in natural populations and distribution of *T. tambroides*, there has been a

pronounced surge of interest in artificial propagation, for aquaculture production and conservation purposes (Ng & Andin, 2011).

The infectious diseases in fish are often caused either by bacteria, fungi, viruses, and parasites. Among them, bacteria pathogens account for the majority of diseases in fish farming (Dhar, 2014). Diverse *Pseudomonas* spp. are pathogenic to fish, resulting in significant economic losses in the aquaculture sector. Fish pathogenic pseudomonads include *Pseudomonas aeruginosa*, *P. putida*, *P. luteola*, *P. fluorescens*, *P. koreensis*, *P. anguilliseptica*, *P. baetica*, *P. chlororaphis*, *P. plecoglossicida*, and *P. pseudoalcaligenes* (Austin & Austin, 2016). The mortality of diseased cultured *Tor tambroides* was associated with *P. koreensis*. The diseased fish displayed scale loss, exophthalmia, abdominal swellings, and some haemorrhaging at the fins and gills (Kho et al., 2023). *P. koreensis* was also described as the causal agent of eye lesions in golden mahseer (*Tor putitora*) from India (Shahi & Mallik, 2014).

The common practice in treating bacterial infections involves the application of antibiotics. However, the long-term use and misuse of antibiotics in the aquaculture industry have reportedly caused many adverse effects on humans, fish, animals, and the environment. For instance, the unregulated use of antibiotics in aquaculture exerted a selective pressure on aquatic bacterial species, and thus generated reservoirs of antibiotic-resistant bacteria (ARB) and antibiotic-resistance genes (ARGs) in the aquatic environment. From these reservoirs, ARB from the aquatic environment may reach humans directly or the ARGs may disseminate to other bacteria through horizontal gene transfer, eventually reaching human pathogens (Amarasiri et al., 2020).

Vaccination is one of the alternatives that have been recommended to be employed in the management of aquaculture as it has been successful in preventing or reducing the
