### Abstract

The present study aimed to explore the influence of adult attachment on relationship quality in parents of children with ADHD. A quantitative method design was used to address the research objective. Two hundred and fifty four (254) participants were employed: 101 parents of children with ADHD, and 153 parents of children without ADHD. Three established questionnaires were used: Connors Parental rating Scale (CPRS), Communication Pattern Questionnaire (CPQ), and Experience in Close Relationship (ECR). The result shows that attachment style moderated the impact of having a child with ADHD on conflict demand and withdraws communication in the couple.
