Supervisor:
Mr. Paul Cliff Simon Divis
Department of Para-Clinical Sciences

Submitted in part fulfillment for the Degree of Bachelor of Medicine in the Faculty of Medicine and Health Sciences Universiti Malaysia Sarawak

April, 2011
ACKNOWLEDGEMENT

There are several people to whom our group owes a debt of thanks and for their guidance throughout the research. First and foremost, our group offers our sincerest gratitude to our supervisor, Mr. Paul Cliff Simon Divis, who proposed the topic of our research of which we have completed, and whose encouragement, supervision and support enabled us to have a better understanding on the topic of parasitology, especially of those extracted from freshwater fish samples.

Secondly, our group is heartily thankful to Madam Norliza Samsuri, a medical laboratory assistant for her time and assistance during dissection of the specimens and morphological identification of the parasites found. Madam Norliza provided the group with other materials needed to conduct the dissection of the specimens. We also thank, Mr. Albert who gave us permission to use the laboratory and facilities.

Thirdly, gratitude is credited to both the Elective 1 Research coordinators, Professor Dr. Mohd Syafiq Bin Abdullah and Dr. Zunika Binti Amit for their dedication in supervising the elective research held for second year UNIMAS Medical students.

Fourthly, it must not be forgotten that our deepest appreciation goes to our parents who lovingly showered us with their moral support, prayers and encouragement.

Lastly, our group offers our regards and blessings to all of those who had offered a helping hand and support in regards to the completion of our research.

To all of whom our group has mentioned above, may bountiful blessings from God be showered upon them always. Amen!

ABSTRACT

Helminthic infection can cause diseases in both man and domestic animals, especially in developing countries. The incidence of parasitic diseases in fish is very common. In particular, of all the known species of helminthes, 30,000 species (including the socio-economic importance) are known from marina and freshwater fishes. However there are no significant studies conducted on helminthic infection in freshwater fish, apart from the other studies done on water creatures such as snail and crab. Since there are minimal studies being conducted on freshwater fish, our group conducted an investigation for the presence of parasites, particularly helminthic parasite in the gastrointestinal tract of freshwater fish. A total of 12 specimens of catfish were randomly selected from a wet market in Kuching, Sarawak from October to December 2010. All the specimens were subjected to examination for gastrointestinal helminthes parasites during that period. The weight and length of the fish were measured prior to dissection. The morphological examinations of the parasites were done under the light microscope. Five out of 12 samples (42%) were found to be positive with gastrointestinal helminthes infection. The dominant parasites found had a higher chance to be from the phylum Nematoda (5 out of 8 samples) and followed by Trematoda (3 out of 8 samples). Out of 4 fertilised female fishes, 3 were found positive with helminthes parasites. Five out of 8 samples (62.5%) were found in the intestine of the fish and 3 (37.5%) were found in the stomach. Our finding indicates that fishes that were breaded in a closed-area or in ponds have higher chances to have a helminthic infection of the gastrointestinal tract compare to opened-area.
