Abstract

We report a case of 10-year-old Indian girl with history of multiple superficial angiomyxoma, presented with three months history of painless right upper lid swelling. There were no visual dysfunctions. Previously, the patient had multiple superficial angiomyxoma (left pinna, left upper cheek, left upper limb, chest, right axilla, hard palate) and epidermal cyst (chin). The histopathological specimens were negative to S-100 protein antibody. Systemic review and family history was unremarkable. Excision biopsy and upper lid reconstruction were performed. Intraoperatively the tumor was multilobulated, firm, well encapsulated and did not invade the underlying tarsal plate. Histopathological features of the upper lid tumor were consistent with nerves sheath myxoma (neurothekeoma). To the best of the authors’ knowledge, this is the first reported case of neurothekeoma in association with multiple superficial angiomyxoma.

Introduction

Myxoma is a benign mesenchymal tumor with a hypocellular, hypovascular, bland appearance, composed of fibroblasts embedded in an abundant myxoid matrix.1

Allen subdivided myxoid lesions into mainstream myxoma and neurothekeoma (nerve sheath myxoma) are mainstream myxomas of soft tissues. The other three entities considered as mainstream myxomas of soft tissues are intramuscular myxoma, juxta-articular myxoma and aggressive angiomyxoma.2 Superficial angiomyxoma arises in the dermis and subcutaneous tissue, and is characterized by prominent thin-walled blood vessels,1 whereas neurothekeoma originates from the peripheral nerve sheath.4 We report a case of neurothekeoma palpebrae in a patient with history of multiple superficial angiomyxoma.

Case Report

A 10-year-old Indian girl presented with three months’ history of painless right upper lid swelling. The tumor began as a small lump involving the lateral half of the upper lid (Figure 1). It underwent gradual enlargement leading to mechanical ptosis which spared the visual axis (Figure 2). There were no visual dysfunctions. Previously, the patient had multiple superficial angiomyxoma (left pinna, left cheek, left upper limb, chest and right axilla, hard palate) and epidermal cyst (chin) (Figure 3). The histopathological specimens were negative to S-100 protein antibody (Figure 4).

Systemic review and family history was unremarkable. Excision biopsy and upper lid reconstruction were performed. Intraoperatively the tumor was multilobulated, firm, well encapsulated and did not invade the underlying tarsal plate. Histopathological features of the upper lid tumor were consistent with nerves sheath myxoma (neurothekeoma) (Figure 5). At 6 months follow up, there is no recurrence.

Discussion

Neurothekeoma palpebrae are extremely rare; only 10 cases have been reported so far.

The average age of presentation is 40-year-old with female preponderance. The tumor is slow growing, painless and often misdiagnosed as...
