UNIVERSITI MALAYSIA SARAWAK

2020

## DECLARATION

I declare that the work in this thesis was carried out in accordance with the regulations of Universiti Malaysia Sarawak. Except where due acknowledgements have been made, the work is that of the author alone. The thesis has not been accepted for any degree and is not concurrently submitted in candidature of any other degree.

## ACKNOWLEDGEMENT

Behind every success, there are one or more persons who have supported directly or indirectly. This dissertation would have not been possible without those mentioned below. And for that, I truly appreciate and treasure every single effort, advice and aid received.

On top of supervising, guiding, advising and teaching, Prof. Dr. Andrew Alek Tuen listened to our problems, tolerated our mistakes, forgave our wrongdoings, and most importantly, loved us like his own children. He is not just a supervisor but also a loving father. If it wasn't for him, I would not be confident to pursue a PhD degree. As he may be aware, along this journey, I was always distracted by other side projects. I appreciate his silent support. My promises of sending him drafts were always delayed, yet he put his full commitment on me and this thesis.

Assoc. Prof. Dr. Mohd. Azlan Jayasilan as my Co-Supervisor, I am grateful for his support direct and indirect, especially the time he brought extra food to help fuel our tired spirits in Kapit! Not forgetting the great opportunity given to me to join the 55<sup>th</sup> Annual Meeting of the Association for Tropical Biology and Conservation (ATBC) in Kuching, Sarawak. It was one of the most memorable meetings, with the world-class researchers.

Not many had the opportunities like I did for the past seven years. Thanks are due to the slimy creatures, the Bornean frogs which gave me the great chance to work with this world-class herpetofauna expert, Prof. Dr. Indraneil Das. I truly appreciate his patience; despite not being registered under his supervision, he taught me unconditionally, shared his experiences and advised me. Dr. Mustafa Rahman, my all-time mentor has no expiry date. His kind and encouraging words gave me the strength to carry on. Above all, I thank him for spending

time to proof-read my thesis. It's a tough job, I know! Dr. Jongkar Grinang, thanks for never saying no to us upon our field-related request, financially and on statistical issues.

I owe a debt of gratitude to Mike Meredith and Ngumbang Juat for enriching my statistical knowledge by involving me in teaching classes. No doubt, the statistic learnt has strengthened this dissertation. I will treasure and remember their advice and suggestions.

To my teammates, Attiqqah Fadziliah Sopian, Khatijah Ismail, Pui Yong Min, Melynda Cheok Ka Yi, Mohd Paizal Wahab, Adi Shabrani Ridzuan and Sally Kaicheen. The journey of completing this would had never been possible without you. The laughs and tears shared with you are the memorable times that I treasure. Thank you for being part of this journey.

Our field assistants, Rahah Mohd Yakup, Mohd Hasri Al-Hafiz Haba, Isa Sait, as Prof. Andrew always said, without you, not a single field trip of this project would have been possible. You are not only the greatest assistants in the field trip, but also hear our problems and provide solutions. Thank you for being angels throughout the project.

To my friends who are so dear to me. Sharifah Mona Abdul Aziz, thanks for being my guarantor when I received my MyBrain scholarship. I couldn't thank you more for having faith in me for not causing you trouble. Izneil Nasriq, how could I possibly make through all those nights staying late in PG room without you! Woon Yea Wen, and Charlene Liew, all my super supportive cousins and my former classmates (yes, you all!!), although distant and not always meeting up, your support never faded in my heart.

Sarawak Energy Berhad for the grant for surveys; Forest Department Sarawak for the research permit 467/2014, 462/2015 which allowed us to carry out the surveys; Land Custody Development Council for the permission using the compound of Pelagus Resort; the local community for the support by helping us uploading and downloading heavy stuff we have, and the companionship throughout the survey. Mr. Win Meluda from Rumah Bujah and Mr. Ugak from Rumah Bein for their assistance during data collection in the field.

My boyfriend, Edward Empaling Anak Juing, words can't describe the endurance and patience of yours and the commitment to this project; your support and companionship all these years during my field works is important in finishing my thesis.

I save the best for last! To my family, I never imagine I can go up this extent. This academic-pursuing journey would never been possible without the support of my beloved family, my father Pang Kee Hien, mummy, Chok Shu Fei, my brothers Pang Mai Gio and Pang Mai Cherng. The greatest love I ever have that never stop, supporting me emotionally and financially. Above all, your faith in me is the biggest motivation that moved me through all the obstacles not only in the journey but also in life.

Finally, to my late uncles, David Pang and Tony Pang. You are always in my heart!

## ABSTRACT

Disturbed habitats tend to have impoverished bird communities compared to primary forests. This research focuses on the group known as babblers (Timaliidae and Pellorneidae) which are currently understudied in terms of how they persist in a multispecies community and what resource partitioning they utilise when in a continuous disturbed habitat. This study demonstrates a method to measure disturbance by quantifying the level of disturbance in selected sampling stations and was measured based on human and plant components. Based on the disturbance index, the disturbance was found to be varied in different forest types in Pelagus, Sarawak. In addition, the study also examined the babbler community and their potential prey in the areas with varying levels of disturbance; identifying which covariate(s) affect both babblers and prey the most. A total of 1,335 individuals of birds from 106 species were captured throughout this study. Amongst them were 328 babbler individuals, consisting of 16 different species representing from two families (Timaliidae and Pellorneidae). Chestnut-winged babbler was the most common species captured. Of the 17 orders of prey captured, Diptera was the most dominant order, followed by Hymenoptera and Coleoptera. Occupancy of babblers in Pelagus was found to be high ( $> 50\%$ ), despite netting probability being low (20%). Within the nine covariates measured with regards to occupancy and netting probability, eight had almost equal influence on babblers, except for the presence of domestic animals, such as dogs and cats, while canopy cover was the most influential covariate affecting prey abundance at all stations. Resource partitioning among babblers was also investigated by deploying double mist-nets with heights indicated by the ascending shelf (maximum height 3.6 m). The numbers of babblers netted was inversely proportionate to the shelf height of the mist-net, lower shelves (0–0.6 m) recorded the highest catches, implying that most babblers prefer to forage closer to the ground, despite the fact that a majority of

potential prey being caught on sticky traps at 1 m and above. Sampling was conducted four times a year, with an interval of two to three months in between. Results show that the collective babbler abundance was significantly greater between March and April of 2016 compared to the other months in the same year, but there was no seasonal marked on prey abundance. This suggests that foraging activity among babblers could be more active compared to other periods as the foraging time was shorten due to raining. Thus, higher number of babblers were captured. The composition of babbler diets was investigated by analysing sample obtained from 110 regurgitated sample, 58 faecal samples and 27 stomach content. Eleven intact prey items were found from the regurgitated samples, while faecal and stomach content had one each. The results showed that babbler in this study are diet-opportunist. and generalists. Their diets constitute of 11 prey groups. Caterpillars appeared to be the most preferred prey (Jacob's Index), while Coleopterans ranked fourth (behind Orthoptera and Araneida), despite being frequently found in the diet samples. Prey body size was not an important factor affecting babbler prey choice, as the regressions between babbler weight against prey body length had no relation. Instead, babblers may be tracking nutrient content. The preferred prey, caterpillars are rich in phosphorus, while Orthopterans have the highest crude protein content. As human-induced disturbance is inevitable, it is critical to understand how bird groups such as babblers and their prey tolerate different levels of disturbance at the community level, and ultimately mitigate the disturbances that may impact other wildlife.

***Pemakanan dan Kepelbagaian Babbler (Timaliidae dan Pellorneidae): Kesan Kemungkinan Gangguan Antropogenik dan Ciri-ciri Alam Sekitar di Pelagus, Sarawak (Malaysia Timur: Borneo)***

**ABSTRAK**

*Dalam mengekalkan hidupan komuniti burung, habitat yang terganggu tidak setanding dengan hutan primer. Kajian ini memfokus pada kumpulan burung babbler mengenai kaedah mereka bertahan dalam komuniti pelbagai spesies dan pembahagian sumber (tempat dan makanan) dalam habitat yang terganggu secara berterusan. Kajian ini menunjukkan kaedah mengukur gangguan dengan mengira tahap gangguan di stesen pensampelan terpilih yang menggunakan komponen manusia dan tumbuhan. Menurut indek gangguan, ia menunjukkan gangguan berbeza di jenis hutan berlainan di Pelagus, Sarawak. Kajian ini juga mengkaji komuniti babbler dan potensi mangsa mereka di kawasan yang mempunyai tahap gangguan yang berbeza; mengenal pasti kovariat yang terbanyak pengaruh terhadap mangsa dan pemangsa. Sejumlah 1335 individu burung daripada 106 spesies telah ditangkap sepanjang kajian ini. Babbler terdiri daripada 328 ekor, 16 spesies dan dua famili (Timaliidae dan Pellorneidae). Chestnut-winged babbler, merupakan spesies yang paling banyak ditangkap. Daripada 17 kumpulan mangsa tangkapan, Diptera paling dominasi, diikuti Hymenoptera dan Coleoptera. Kemungkinan babbler yang menghuni di Pelagus tinggi (melebihi 50%) walaupun kebarangkalian penangkapan rendah (kurang daripada 20%). Lapan kovariat mempunyai pengaruh yang hampir sama pada kebarangkalian penghunian dan penangkapan babbler, kecuali dalam kehadiran haiwan domestik seperti anjing dan kucing manakala penutup kanopi hutan adalah kovariat yang paling mempengaruhi potensi mangsa di semua stesen. Pembahagian sumber di kalangan babbler juga dikaji menggunakan jaring berganda dengan ketinggian maksimum 3.6 m. Bilangan babbler yang tertangkap pada jaring dengan ketinggian 0–0.6 m adalah tertinggi,*

menunjukkan bahawa babbler mencari makanan berdekatan tanah walaupun kebanyakan mangsa ditangkap pada perangkap pelekat pada aras 1 m dan ke atas. Pensampelan dilakukan empat kali setahun berselang dua – tiga bulan. Hasil menunjukkan bahawa kelimpahan kolektif babbler adalah lebih tinggi pada Mac dan April 2016 berbanding dengan tiga tempoh lain tetapi tiada corak temporal yang ketara untuk kelimpahan mangsa. Aktiviti pencarian makanan mungkin lebih aktif dikalangan babbler. Ini kerana waktu pencarian makanan dipendekkan disebabkan hujan. Justeru, lebih banyak babbler terperangkap. Komposisi diet makanan babbler disiasat dengan menganalisis 110 sampel muntah, 58 sampel tahi dan 27 kandungan perut. Sebelas penemuan mangsa yang belum dihadam didapati dari sampel muntah, manakala setiap satu dari tahi dan kandunagn perut. Hasil kajian menunjukkan bahawa babbler adalah pemakan umum and berkesempatan. Diet pemakanan babbler terdiri daripada 11 kumpulan mangsa. Ulat bulu adalah mangsa paling digemari menurut Indeks Jacob manakala Coleoptera menduduki tempat keempat walaupun paling kerap dijumpai dalam sampel diet. Analisis juga menunjukkan bahawa saiz badan mangsa bukanlah faktor mempengaruhi pilihan pemangsa babbler kerana regresi antara berat badan babbler terhadap bahagian badan mangsa diukur mempunyai korelasi yang tidak ketara. Sebaliknya, pemilihan mungkin berdasarkan kandungan zat. Ulat bulu kaya dengan fosforus, manakala Orthoptera mempunyai kandungan protein yang tinggi. Oleh kerana gangguan yang disebabkan oleh manusia tidak dapat dielakkan, pemahaman kumpulan babbler dan mangsa mereka mengatasi tahap gangguan yang berbeza di peringkat komuniti dan akhirnya mengurangkan gangguan yang mungkin memberi kesan kepada hidupan liar yang lain adalah penting..
