ABSTRACT

Introduction: Nursing documentation is the key to nursing care in hospitals. Nursing documentation contains evidences which demonstrate a significant association between the comprehensive level of nursing care and nurses' professional practice. Therefore, nurses in Malaysia are trained to abide with the code of professional practice (1998) which required them to contrive a complete and comprehensive nursing documentation. Despite the importance of nursing documentation in the nursing professional practice, such study almost non-existent in Malaysia. Hence, there is a need to explore nurses understanding about existence of professionalism within their documentation, from a Malaysian context. **Methods:** The study utilized a qualitative approach which aimed to explore the perceptions among nurses in Malaysia on their documentation with relation to professionalism in nursing. Forty semi structured interviews were conducted in order to obtain an understanding of nurses' views on their documentation and its influence on their ways of preparing and completing their documentation. Thematic analysis was used to identify categories and themes in nurses' accounts of their documentation with relation to professionalism in nursing. **Results:** One of many profound findings from the study is the fear among nurses of "blaming culture" in that occurs their clinical setting. The nurses perceive "blaming culture" do not tolerate mistakes and they are more likely to be blamed for poor patient safety and insufficient quality of care. This is because nurses are directly involved in delivering care to patient or client in the hospital. "Blaming culture" however motivates nurses to ensure their documentation is complete, comprehensive and contemporaneous. **Conclusion:** Interestingly, the nurses perceive their documentation as an important evidence if there are possible future medical legal issues that they might have to involve with.

ABSTRACT

Introduction: Vaping is a use of electronic devices which do not produce smoke or steam, rather an aerosol consisting of fine particles, containing varying amounts of propylene glycol, glycerine, flavourings and other chemicals. It is battery-powered devices that mimic the action of smoking. In Malaysia, vaping has become a major trend. Videos are going viral on social media showing school students in uniform proudly puffing away. The aim of this study was to find out the acceptance of vaping among medical and nursing students. **Methods:** A descriptive cross-sectional study with multiple stage of sampling technique on population of 624 medical and nursing students. Total samples were 389, by Krejci Morgan (1970) sampling technique. Structured questionnaires by A. Gorukanti (2018) with 15 items consisted of knowledge, attitude and acceptance and attitude and believe as data collection tools. **Results:** Results showed 9% to 10% of respondents are still smoking, they believed e- cigarette is safe and would not affect one's health, as it is a water-based product trademarked. They also regard e-cigarette a way of quitting or cutting down smoking. **Conclusion:** 10% of respondents consistently believed e-cigarettes is harmless. Although the percentage may look small but the impact on the public is huge. However, 90% strongly agreed e-cigarettes 'vapour is dangerous to babies and kids. What concerns us is the consistent group of the 10%, are students who will become our healthcare providers in the future. Their strong-belief in vaping will influence the future of the public understanding, "If doctors and nurses said vaping is safe ... it is safe... right? why not. which is harmful. However, this study has impelled us not only to look at the strength and the significance outcomes of study and neglecting the trifle ones that may prime to serious healthcare consequences of the future society.
